

Hashing | Maps | Time complexity | Collisions | Division Rule of Hashing

Hashing

1	2	1	3	2
---	---	---	---	---

How many times 1 appears = 2
 " 2 " = 1
 " 4 " = 0

int f(number) {

 cnt = 0;

 for i = 0; i < n; i++) {

 if (arr[i] == number) {

 cnt++;

}

 return cnt;

}

Time complexity : $O(N)$

$(10^8$ operations take 1 sec)
to execute

Time complexity $O(Q \times N)$

pre-storing / fetching

0	1	2	3	4	5	6	7	8	9	10	11	12
0	1	2	3	1	5	6	7	8	9	10	0	0

hash array

→ in index 1 & 2, it appears twice

so as we traverse the array, the count (pre-calculation) is done / updated.

$$\text{hash}[1] = 2$$

$$\text{hash}[2] = 2$$

$$\text{hash}[3] = 1$$

$$\text{hash}[10] = 0$$

```
#include <iostream>
```

```
using namespace std;
```

```
int main() {
```

5

```
    int n;
```

```
    cin >> n;
```

all
[1, 3, 2, 1, 3]

```
    int arr[n];
```

for (int i=0; i<n; i++) cin >> arr[i];

~~for~~ // precompute

```
int hash[13];
```

= {0}

hash size = 12

[0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0]

12 elements

```
for (int i=0; i<n; i++) {
```

hash[arr[i]] += 1;

hash[1] += 1

[0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0]

1 1 1

2 3

hash[2] += 1

hash[1] += 1

hash[3] += 1

int q;

5

```
cin >> q;
```

```
while (q--) {
```

```
    int number;
```

input output

1 → 2

4 → 0

2 → 1

3 → ½

½ → 0

// fetch

cout << hash[number] << endl;

}

either 0;

}

Note:- max array size is 10^7 ✓

arr [$\underbrace{10^9}_{\text{size}} + 1$] X segmentation fault

Inside main, max array size is 10^6 because if size is greater than that it cannot allocate that much memory size.

Note: If array is declared globally i.e. outside above main function,
 the size can be max 10^7 i.e. $\text{arr}[10^7]$
 (for int)

* CHARACTER COUNTING.

Using arrays

$s = "a b c d \otimes ab ef c"$
 (only lowercase letters say)
Method 1 - using arrays
 $f(\text{char } c, s) \{$

a appears 2

$$\begin{aligned} a &\rightarrow 2 \\ c &\rightarrow 2 \\ z &\rightarrow 0 \end{aligned}$$

! Queries
can be asked.

cnt = 0;
 for (int i=0; i < n; i++) {
 if ($s[i] == c$)
 cnt++;

T.C = $O(Q \times N)$

}
 return cnt;

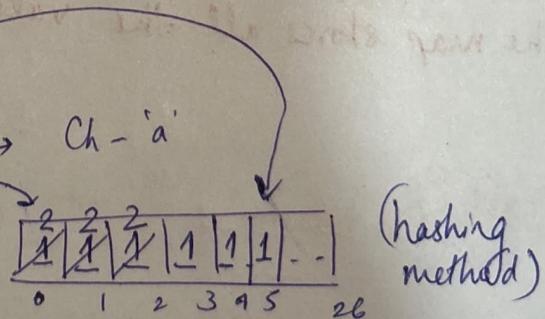

}

Method 2 - Using hashing

'a' $\rightarrow 97$

'z' $\rightarrow 122$

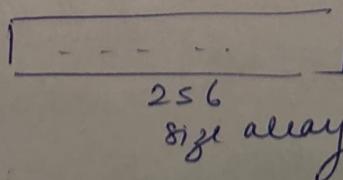

$f \rightarrow 'f' - 'a' = 102 - 97 = 5$
 a $\rightarrow 'a' - 'a' = 0$
 no. of lowercase letters = 26
 $\text{arr}[26]$

* In case string had other characters as well - just take full ASCII table i.e. 256 characters $\text{arr}[256]$

'a' $\rightarrow 97$

'b' $\rightarrow 98$

* Drawback in Number Hashing

In number hashing, hashing into arrays can only be done to at max 10^7 . Thus for numbers having size $> 10^7$ i.e. $10^9, 10^{12}$ etc, we cannot hash it using arrays.

Thus to solve this, in C++, STL comes in & in Java, Collection comes in.

- 1) map
- 2) unordered map → pair<int, int>
cannot be used here.

* MAPS

arr = 1, 2, 3, 1, 3, 2, 12 unordered-map
 $\uparrow \uparrow \uparrow \uparrow \uparrow$
map <key, value>
number frequency

	npp[1]++;
(12→1)	npp{arr[i]}++
(3→1)	
(2→1)	
(1→1)	

Map will just store the elements that are eq. Thus a full sized array is not required to be declared.

Thus it is a bit faster & efficient.

Note: The map stores all the values in sorted order.

```
#include <iostream>
```

```
using namespace std;
```

```
int main () {
```

```
    int n; int arr[n];
```

```
    cin >> n;
```

```
    for (int i=0; i<n; i++) {
```

```
        cin >> arr[i];
```

```
}
```

Initializes array of size 'n'.

e.g.

(5)

[1, 2, 2, 3, 3]

```
// pre-computation of frequency of each element
```

```
map<int, int> mpp;
```

```
for (int i=0; i<n; i++) {
```

```
    mpp[arr[i]];
```

```
}
```

/* point OR iterate in the map

```
int q;
```

```
cin >> q;
```

```
while (q--) {
```

```
    int num; 2, 3, 4
```

```
    cin >> num;
```

```
    cout << mpp[num] << endl;
```

```
}
```

```
when 0;
```

2, 2, 0

a map 'mpp' used to store freq of each element in array

1 → 1
2 → 2
3 → 2

(key, value pair)

wee inputs an integer 'num'
and for each num, outputs
a freq of 'num' by fetching
it from map
mpp [num]

```
for (auto it : mpp) {  
    cout << it.first << " -> " << it.second << endl;
```

same method used in
chacke hashing question. (see code)

Time complexity \rightarrow map

Storing & fetching in a map $\rightarrow \log N$ no. of elements in a map for all cases
 best, avg, worst

Unordered Map

3 \rightarrow 2

12 \rightarrow 1

2 \rightarrow 2

4 \rightarrow 1

} not in order.

In unordered map, storing & fetching \rightarrow

average case $\rightarrow O(1)$
 best case $\rightarrow \underline{O(1)}$

worst case $\rightarrow O(N)$
 very large case $\rightarrow \frac{\text{no. of elements in map}}{N}$

happens because of collisions

★ HASHING METHODS

.) Division Method (LINEAR CHAINING)

.) Folding Method

.) Mid Square Method { not required }

{ 2, 5, 16, 28, 139 }

say array size 10 not allowed

arr[i] \times 10

0	1	1	1	1	1	1	1	1	1	1
2	5	16	28	139	38	48	28	18	6	7

$139 \times 10 = 9$

2 \rightarrow 2

3

4

5 \rightarrow 5

6 \rightarrow 16

7 \rightarrow 18 \rightarrow 28 \rightarrow 28
 8 \rightarrow 28 \rightarrow 38 \rightarrow 48 ~~228~~

9 \rightarrow 139

If someone asks how many times 28 appears,
 apply search algo on 1/8 line and
 thus the task would be performed
 in minimal time!
